Chapter 15

Software Reuse

Learning Objectives

15.1 The reuse landscape

15.2 Application frameworks

15.3 Software product lines

15.4 Application system reuse

Software Reuse

- In most engineering disciplines, systems are designed by composing existing components that have been used in other systems.

- Software engineering has been more focused on original development but it is now recognised that to achieve better software, more quickly and at lower cost, we need a design process that is based on systematic software reuse.

- There has been a major switch to reuse-based development over the past 20 years.

Reuse-based Software Engineering

- System reuse
  - Complete systems, which may include several application programs may be reused as part of a system of systems.

- Application reuse
  - An application may be reused by incorporating it without change into other systems or by configuring the application for different customers.

- Component reuse
  - Components of an application from sub-systems to single objects may be reused.

- Object and function reuse
  - Small-scale software components that implement a single well-defined object or function may be reused.

Reuse-based Software Engineering

- Rather than reuse the code, however, you can reuse the ideas that are the basis of the software. This is called *concept reuse*.

- The concept that you reuse is represented in an abstract notation, such as a system model, which does not include implementation detail.

- Concept reuse is embodied in approaches such as design patterns, configurable system products, and program generators.

- When concepts are reused, the reuse process must include an activity where the abstract concepts are instantiated to create executable components.

Benefits of Software Reuse

Benefit	Explanation
Accelerated development	Bringing a system to market as early as possible is often more important than overall development costs. Reusing software can speed up system production because both development and validation time may be reduced.
Effective use of specialists	Instead of doing the same work over and over again, application specialists can develop reusable software that encapsulates their knowledge.
Increased dependability	Reused software, which has been tried and tested in working systems, should be more dependable than new software. Its design and implementation faults should have been found and fixed.

Benefits of Software Reuse

Benefit	Explanation
Lower development costs	Development costs are proportional to the size of the software being developed. Reusing software means that fewer lines of code have to be written.
Reduced process risk	The cost of existing software is already known, whereas the costs of development are always a matter of judgment. This is an important factor for project management because it reduces the margin of error in project cost estimation. This is particularly true when relatively large software components such as subsystems are reused.
Standards compliance	Some standards, such as user interface standards, can be implemented as a set of reusable components. For example, if menus in a user interface are implemented using reusable components, all applications present the same menu formats to users. The use of standard user interfaces improves dependability because users make fewer mistakes when presented with a familiar interface.

Problems with Reuse

| Problem	Explanation
Creating, maintaining, and using a component library	Populating a reusable component library and ensuring the software developers can use this library can be expensive. Development processes have to be adapted to ensure that the library is used.
Finding, understanding, and adapting reusable components	Software components have to be discovered in a library, understood and, sometimes, adapted to work in a new environment. Engineers must be reasonably confident of finding a component in the library before they include a component search as part of their normal development process.
Increased maintenance costs	If the source code of a reused software system or component is not available, then maintenance costs may be higher because the reused elements of the system may become increasingly incompatible with system changes.

Problems with Reuse

Problem	Explanation
Lack of tool support	Some software tools do not support development with reuse. It may be difficult or impossible to integrate these tools with a component library system. The software process assumed by these tools may not take reuse into account. This is particularly true for tools that support embedded systems engineering, less so for object-oriented development tools.
Not-invented-here syndrome	Some software engineers prefer to rewrite components because they believe they can improve on them. This is partly to do with trust and partly to do with the fact that writing original software is seen as more challenging than reusing other people's software.

The Reuse Landscape

Pearson

The Reuse Landscape

- Although reuse is often simply thought of as the reuse of system components, there are many different approaches to reuse that may be used.

- Reuse is possible at a range of levels from simple functions to complete application systems.

- The reuse landscape covers the range of possible reuse techniques.

The Reuse Landscape

Design patterns

Architectural patterns

Application frameworks

Software product lines

Application system integration

ERP systems

Systems of systems

Configurable application systems

Legacy system wrapping

Component-based software engineering

Model-driven engineering

Service-oriented systems

Aspect-oriented software engineering

Program generators

Program libraries

Approaches That Support Software Reuse

Approach	Description
Application frameworks	Collections of abstract and concrete classes are adapted and extended to create application systems.
Application system integration	Two or more application systems are integrated to provide extended functionality
Architectural patterns	Standard software architectures that support common types of application system are used as the basis of applications.
Aspect-oriented software development	Shared components are woven into an application at different places when the program is compiled.
Component-based software engineering	Systems are developed by integrating components (collections of objects) that conform to component-model standards.

Approaches That Support Software Reuse

Approach	Description
Configurable application systems	Domain-specific systems are designed so that they can be configured to the needs of specific system customers.
Design patterns	Generic abstractions that occur across applications are represented as design patterns showing abstract and concrete objects and interactions.
ERP systems	Large-scale systems that encapsulate generic business functionality and rules are configured for an organization.
Legacy system wrapping	Legacy systems are 'wrapped' by defining a set of interfaces and providing access to these legacy systems through these interfaces.
Model-driven engineering	Software is represented as domain models and implementation independent models and code is generated from these models.

Approaches That Support Software Reuse

Approach	Description
Program generators	A generator system embeds knowledge of a type of application and is used to generate systems in that domain from a user-supplied system model.
Program libraries	Class and function libraries that implement commonly used abstractions are available for reuse.
Service-oriented systems	Systems are developed by linking shared services, which may be externally provided.
Software product lines	An application type is generalized around a common architecture so that it can be adapted for different customers.
Systems of systems	Two or more distributed systems are integrated to create a new system.

Reuse Planning Factors

- The development schedule for the software
  - If the software has to be developed quickly, you should try to reuse complete systems rather than individual components.

- The expected software lifetime
  - If you are developing a long-lifetime system, you should focus on the maintainability of the system.

- The background, skills and experience of the development team
  - All reuse technologies are fairly complex, and you need quite a lot of time to understand and use them effectively.

Reuse Planning Factors

- The criticality of the software and its non-functional requirements
    - For a critical system that has to be certified by an external regulator you may have to create a safety or security case for the system.

- The application domain
    - In many application domains, such as manufacturing and medical information systems, there are generic products that may be reused by configuring them to a local situation. This is one of the most effective approaches to reuse, and it is almost always cheaper to buy rather than build a new system.

- The execution platform for the software

Application Frameworks

Framework Definition

"..an integrated set of software artefacts (such as classes, objects and components) that collaborate to provide a reusable architecture for a family of related applications."

- One of the key benefits of using an object-oriented approach was that objects could be reused in different systems.

- It has now become clear that object-oriented reuse is best supported in an OO development process through larger-grain abstractions called frameworks.

- As the name suggests, a framework is a generic structure that is extended to create a more specific subsystem or application.

Frameworks

- Frameworks provide support for generic features that are likely to be used in all applications of a similar type.

- It is then left to the developer to specialize these by adding specific functionality for a particular application.

- Frameworks support design reuse in that they provide a skeleton architecture for the application as well as the reuse of specific classes in the system.

- Frameworks are implemented as a collection of concrete and abstract object classes in an object-oriented programming language. Therefore, frameworks are language-specific.

Application Frameworks

- Frameworks are moderately large entities that can be reused. They are somewhere between system and component reuse.

- Frameworks are a sub-system design made up of a collection of abstract and concrete classes and the interfaces between them.

- The sub-system is implemented by adding components to fill in parts of the design and by instantiating the abstract classes in the framework.

Web Application Frameworks

- Support the construction of dynamic websites as a front-end for web applications.

- WAFs are now available for all of the commonly used web programming languages e.g. Java, Python, Ruby, etc.

- The architecture of a WAF is usually based on the Model-View-Controller composite pattern.

Model-View Controller

- System infrastructure framework for GUI design.

- Allows for multiple presentations of an object and separate interactions with these presentations.

- MVC framework involves the instantiation of a number of patterns.

The Model-View-Controller Pattern
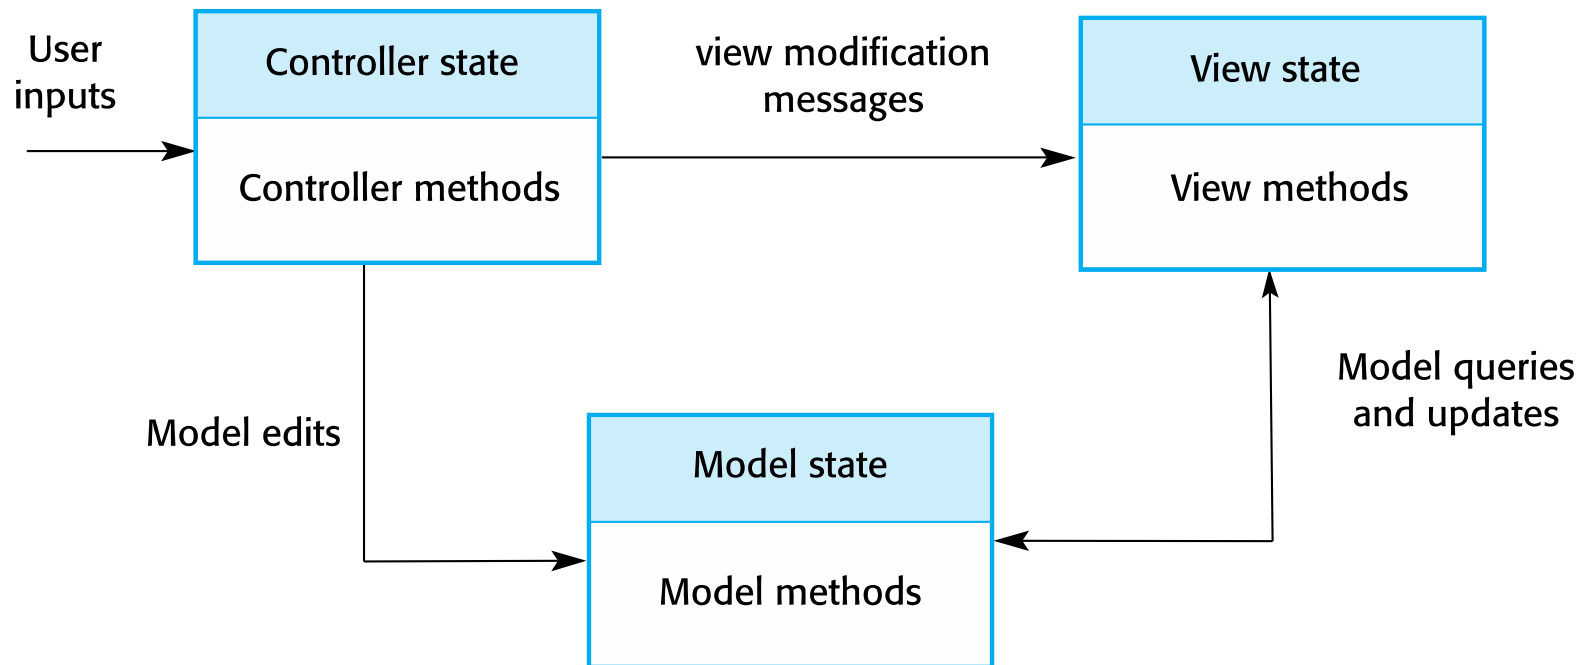

WAF Features

- Security
  - WAFs may include classes to help implement user authentication (login) and access.

- Dynamic web pages
  - Classes are provided to help you define web page templates and to populate these dynamically from the system database.

- Database support
  - The framework may provide classes that provide an abstract interface to different databases.

WAF Features

- Session management
  - Classes to create and manage sessions (a number of interactions with the system by a user) are usually part of a WAF.

- User interaction
  - Most web frameworks now provide AJAX and/or HTML5 support, which allows more interactive web pages to be created.

Implementing via Frameworks

- To implement a system using a framework, you add concrete classes that inherit operations from abstract classes in the framework.

- In addition, you define "callbacks"— methods that are called in response to events recognized by the framework.

- The framework objects, rather than the application-specific objects, are responsible for control in the system which is called "inversion of control".

- In response to events from the user interface and database framework objects invoke "hook methods" that are then linked to user-provided functionality.

Inversion of Control in Frameworks
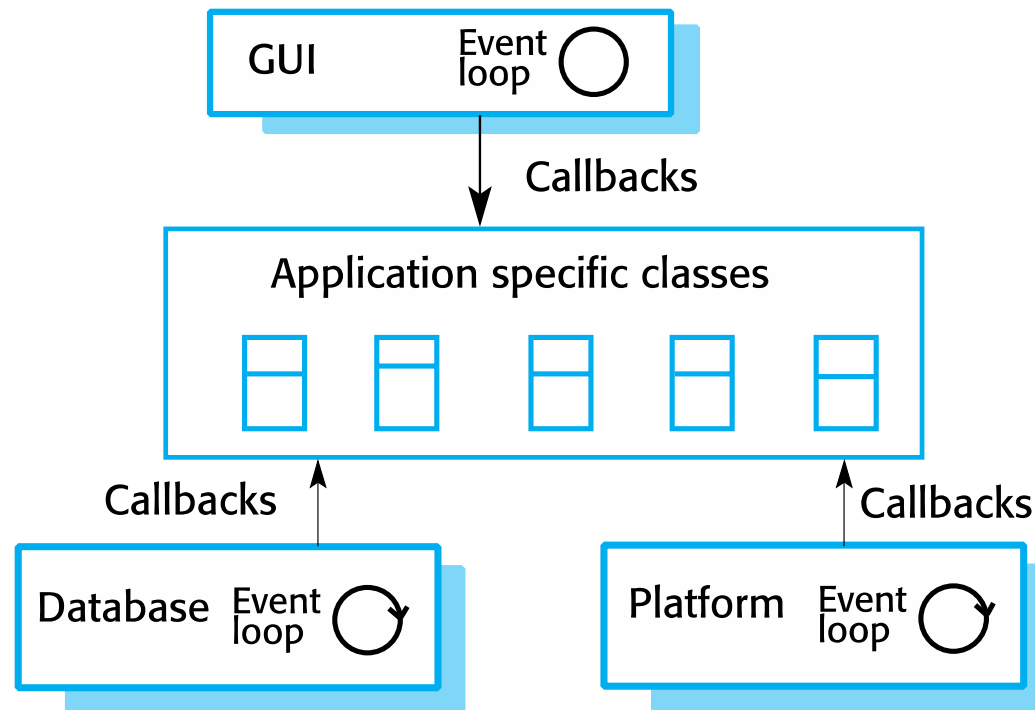

Framework Classes

- System infrastructure frameworks
  - Support the development of system infrastructures such as communications, user interfaces and compilers.

- Middleware integration frameworks
  - Standards and classes that support component communication and information exchange.

- Enterprise application frameworks
  - Support the development of specific types of application such as telecommunications or financial systems.

Frameworks

- Applications that are constructed using frameworks can be the basis for further reuse through the concept of software product lines or application families.

- Because these applications are constructed using a framework, modifying family members to create instances of the system is often a straightforward process.

- It involves rewriting concrete classes and methods that you have added to the framework.

Frameworks Disadvantages

- They are expensive to introduce into software development processes as they are inherently complex and it can take several months to learn to use them.

- Debugging framework-based applications is more difficult than debugging original code because you may not understand how the framework methods interact.

- Debugging tools may provide information about the reused framework components, which the developer does not understand.

Software Product Lines

Pearson

Software Product Lines

- A software product line is a set of applications with a common architecture and shared components, with each application specialized to reflect different requirements.

- Software product lines or application families are applications with generic functionality that can be adapted and configured for use in a specific context.

- Adaptation may involve:
  - Component and system configuration;
  - Adding new components to the system;
  - Selecting from a library of existing components;
 - Modifying components to meet new requirements.

Software Product Lines

- Developing applications by adapting a generic version of the application means that a high proportion of the application code is reused in each system.

- Testing is simplified because tests for large parts of the application may also be reused, thus reducing the overall application development time.

Software Product Lines

- Software product lines usually emerge from existing applications. That is, an organization develops an application and then, when a similar system is required, informally reuses code from this in the new application.

- However, change tends to corrupt application structure so, as more new instances are developed, it becomes increasingly difficult to create a new version.

- Consequently, a decision to design a generic product line may then be made.

Base Systems for a Software Product Line

Specialized application components

Configurable application components
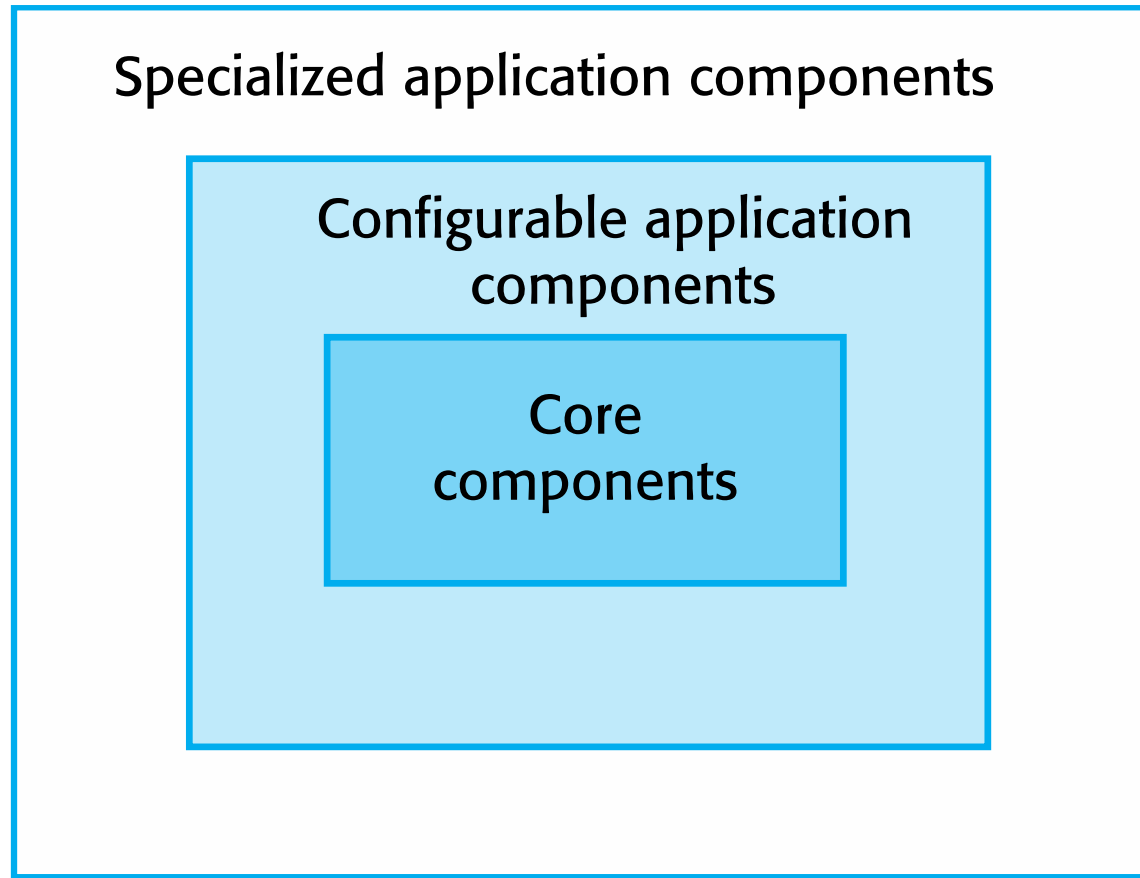

Core components

Base Applications

- Core components that provide infrastructure support. These are not usually modified when developing a new instance of the product line.

- Configurable components that may be modified and configured to specialize them to a new application. Sometimes, it is possible to reconfigure these components without changing their code by using a built-in component configuration language.

- Specialized, domain-specific components some or all of which may be replaced when a new instance of a product line is created.

Application Frameworks and Product Lines

- Application frameworks rely on object-oriented features such as inheritance and polymorphism to implement extensions. Product lines need not be object-oriented.

- Application frameworks focus on providing technical rather than domain-specific support. Product lines embed domain and platform information.

- Product lines often control applications for equipment. Application frameworks are usually software-oriented.

- Software product lines are made up of a family of related applications, usually owned by the same organization.

Product Line Architectures

- If you are developing a software product line using an object-oriented programming language, then you may use an application framework as a basis for the system.

- You create the core of the product line by extending the framework with domain-specific components using its built-in mechanisms.

- There is then a second phase of development where versions of the system for different customers are created.

Product Line Architectures

- Architectures must be structured in such a way to separate different sub-systems and to allow them to be modified.

- The architecture should also separate entities and their descriptions and the higher levels in the system access entities through descriptions rather than directly.

The Architecture of a Resource Allocation System

Interaction

User interface

I/O management

User authentication	Resource delivery	Query management

Resource management

Resource tracking	Resource policy control	Resource allocation

Database management

Transaction management

Resource database

Pearson

The Product Line Architecture of a Vehicle Dispatcher

Interaction

| Operator interface	Comms system interface

I/O management

Operator authentication	Map and route planner	Report generator	Query manager

Resource management

Vehicle status manager	Incident logger	Vehicle despatcher	Equipment manager	Vehicle locator

Database management

| Equipment database	Transaction management	Incident log
	Vehicle database	Map database

The Product Line Architecture of a Vehicle Dispatcher

- At the *interaction level*, components provide an operator display interface and an interface with the communications systems used.

- At the *I/O management level*, components handle operator authentication, generate reports of incidents and vehicles dispatched, support map output and route planning, and provide a mechanism for operators to query the system databases.

- At the *resource management level*, components allow vehicles to be located and dispatched, update the status of vehicles and equipment, and log details of incidents.

- At the *database level*, as well as the usual transaction management support, there are separate databases of vehicles, equipment, and maps.

Product Line Specialisation

- Platform specialization
  - Different versions of the application are developed for different platforms.

- Environment specialization
  - Different versions of the application are created to handle different operating environments e.g. different types of communication equipment.

- Functional specialization
  - Different versions of the application are created for customers with different requirements.

- Process specialization
  - Different versions of the application are created to support different business processes.

Product Instance Development
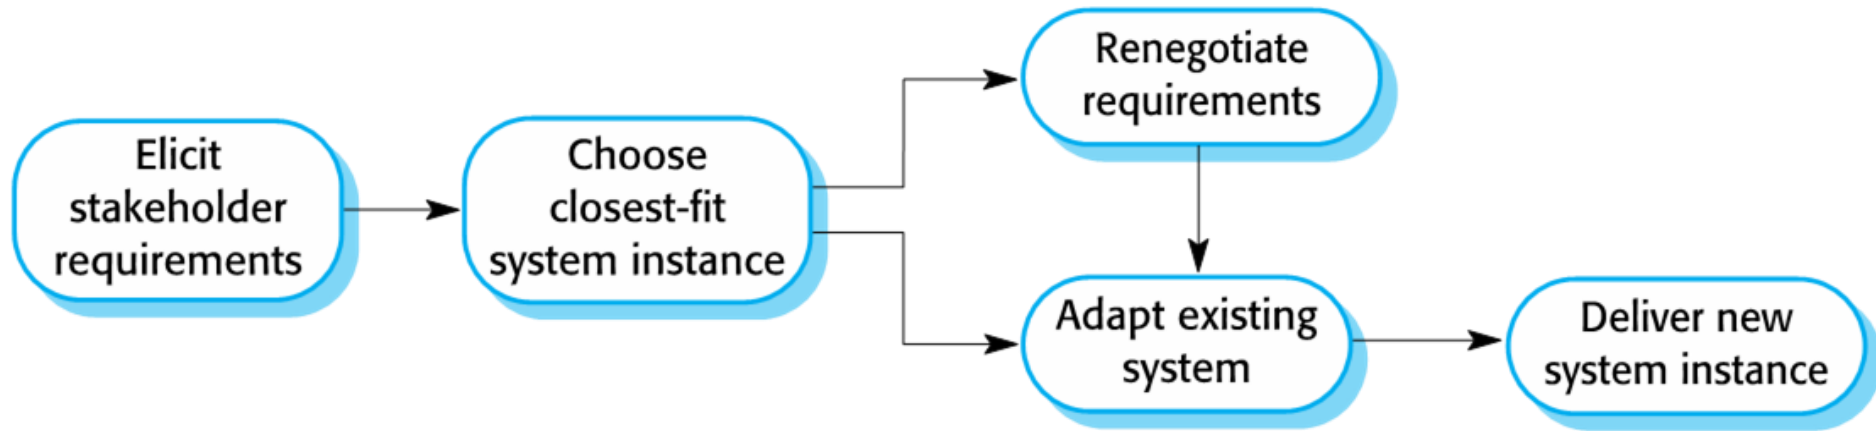

Product Instance Development

- Elicit stakeholder requirements
  - Use existing family member as a prototype

- Choose closest-fit family member
  - Find the family member that best meets the requirements

- Re-negotiate requirements
  - Adapt requirements as necessary to capabilities of the software

- Adapt existing system
  - Develop new modules and make changes for family member

- Deliver new family member
  - Document key features for further member development

Pearson

Product Instance Development

- When you create a new member of a product line, you may have to find a compromise between reusing as much of the generic application as possible and satisfying detailed stakeholder requirements.

- The more detailed the system requirements, the less likely it is that the existing components will meet these requirements.

- However, if stakeholders are willing to be flexible and to limit the system modifications that are required, you can usually deliver the system more quickly and at a lower cost.

Product Line Configuration

- Design time configuration
  - The organization that is developing the software modifies a common product line core by developing, selecting or adapting components to create a new system for a customer.

- Deployment time configuration
  - A generic system is designed for configuration by a customer or consultants working with the customer. Knowledge of the customer's specific requirements and the system's operating environment is embedded in configuration data that are used by the generic system.

Design Time Configuration

- When a system is configured at design time, the supplier starts with either a generic system or an existing product instance.

- By modifying and extending modules in this system, the supplier creates a specific system that delivers the required customer functionality.

- Design-time configuration is used when it is impossible to use the existing deployment-time configuration facilities in a system to develop a new system version.

- However, over time, when you have created several family members with comparable functionality, you may decide to refactor the core product line to include functionality that has been implemented in several application family members.

Deployment-Time Configuration
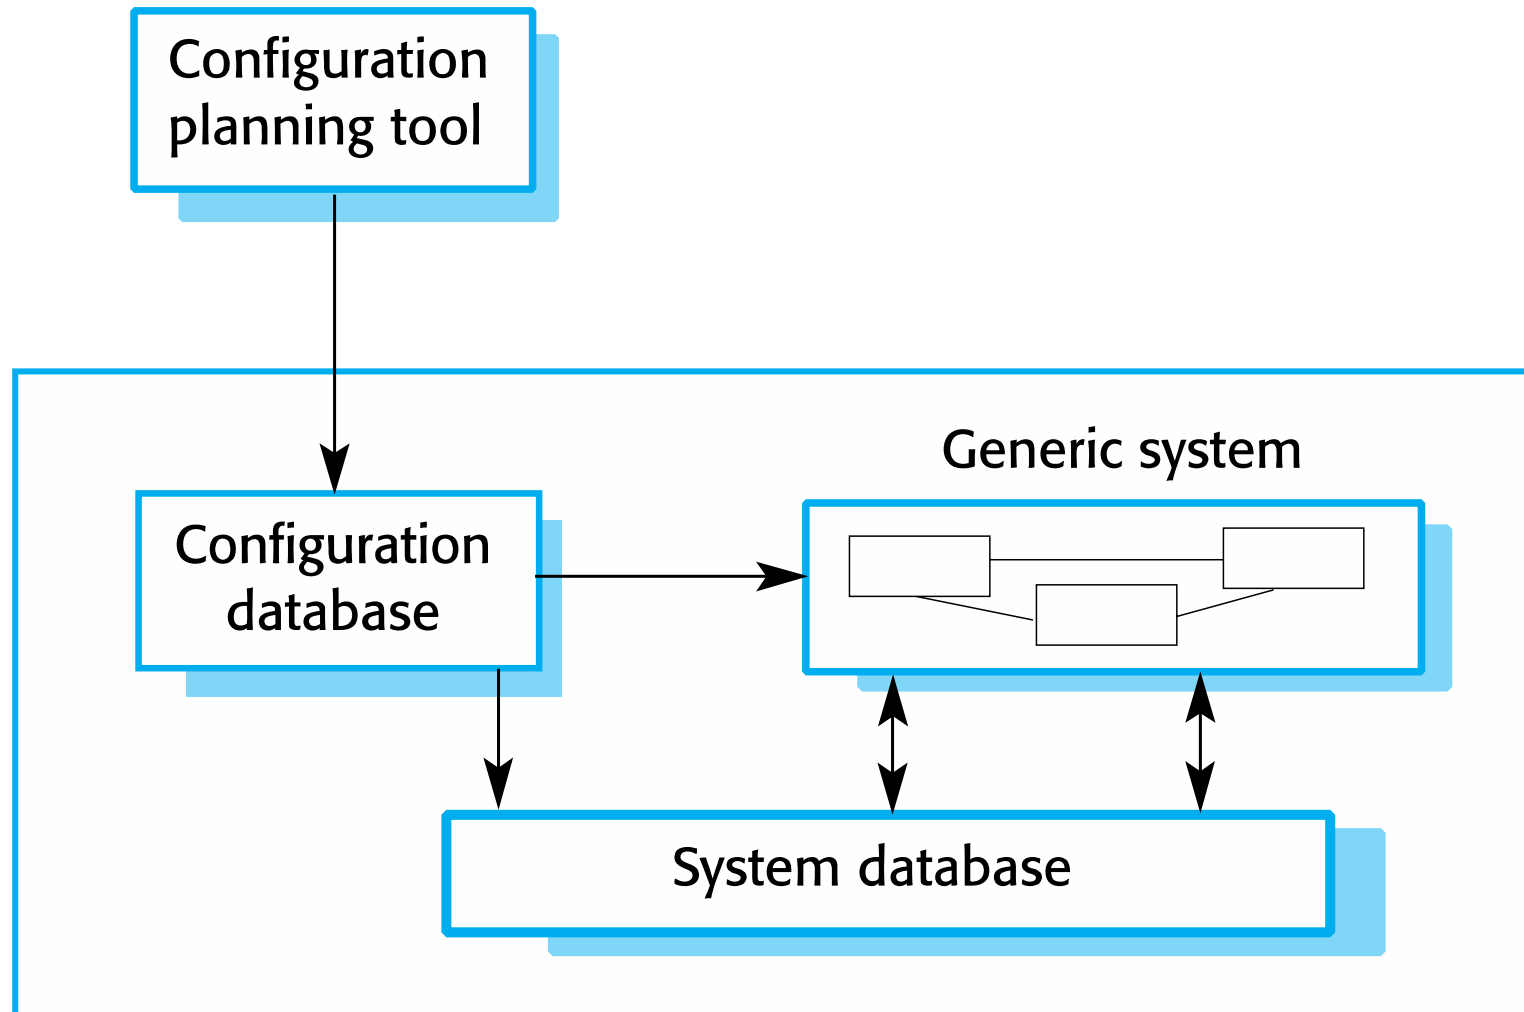

Levels of Deployment Time Configuration

- *Component selection*, where you select the modules in a system that provide the required functionality.

- *Workflow and rule definition*, where you define workflows (how information is processed, stage-by-stage) and validation rules that should apply to information entered by users or generated by the system.

- *Parameter definition*, where you specify the values of specific system parameters that reflect the instance of the application that you are creating

Application System Reuse

Application System Reuse

- An application system product is a software system that can be adapted for different customers without changing the source code of the system.

- Application systems have generic features and so can be used/reused in different environments.

- Application system products are adapted by using built-in configuration mechanisms that allow the functionality of the system to be tailored to specific customer needs.

  – For example, in a hospital patient record system, separate input forms and output reports might be defined for different types of patient.

Benefits of Application System Reuse

- As with other types of reuse, more rapid deployment of a reliable system may be possible.

- It is possible to see what functionality is provided by the applications and so it is easier to judge whether or not they are likely to be suitable.

- Some development risks are avoided by using existing software.

- Businesses can focus on their core activity without having to devote a lot of resources to IT systems development.

- As operating platforms evolve, technology updates may be simplified as these are the responsibility of the COTS product vendor rather than the customer.

Problems of Application System Reuse

- Requirements usually have to be adapted to reflect the functionality and mode of operation of the COTS product.

- The COTS product may be based on assumptions that are practically impossible to change.

- Choosing the right COTS system for an enterprise can be a difficult process, especially as many COTS products are not well documented.

- There may be a lack of local expertise to support systems development.

- The COTS product vendor controls system support and evolution.

COTS-Solution and COTS-Integrated Systems

| Configurable application systems	Application system integration
Single product that provides the functionality required by a customer	Several heterogeneous system products are integrated to provide customized functionality
Based around a generic solution and standardized processes	Flexible solutions may be developed for customer processes
Development focus is on system configuration	Development focus is on system integration
System vendor is responsible for maintenance	System owner is responsible for maintenance
System vendor provides the platform for the system	System owner provides the platform for the system

Configurable Application Systems

- Configurable application systems are generic application systems that may be designed to support a particular business type, business activity or, sometimes, a complete business enterprise.

  – For example, an application system may be produced for dentists that handles appointments, dental records, patient recall, etc.

- Domain-specific systems, such as systems to support a business function (e.g. document management) provide functionality that is likely to be required by a range of potential users.

ERP Systems

- An Enterprise Resource Planning (ERP) system is a generic system that supports common business processes such as ordering and invoicing, manufacturing, etc.

- These are very widely used in large companies - they represent probably the most common form of software reuse.

- The generic core is adapted by including modules and by incorporating knowledge of business processes and rules.

The Architecture of An ERP System

```
Purchasing          Supply chain          Logistics          CRM

Processes           Processes             Processes          Processes
```

Business rules

System database

Pearson

ERP Architecture

- A number of modules to support different business functions.

- A defined set of business processes, associated with each module, which relate to activities in that module.

- A common database that maintains information about all related business functions.

- A set of business rules that apply to all data in the database. Therefore, when data is input from one function, these rules should ensure that it is consistent with the data required by other functions.

ERP Limitations

- The functionality of the customer's application is restricted to the functionality of the ERP system's built-in modules.

- The buyer company's processes and operations have to be defined in the ERP system's configuration language.
  - This language embeds the understanding of business processes as seen by the system vendor, and there may be a mismatch between these assumptions and the concepts and processes used in the customer's business.

ERP Configuration

- Selecting the required functionality from the system.

- Establishing a data model that defines how the organization's data will be structured in the system database.

- Defining business rules that apply to that data.

- Defining the expected interactions with external systems.

- Designing the input forms and the output reports generated by the system.

- Designing new business processes that conform to the underlying process model supported by the system.

- Setting parameters that define how the system is deployed on its underlying platform.

Configurable Application Systems Testing

- Testing is a major problem when systems are configured rather than programmed using a conventional language.

- Test automation may be difficult or impossible. There may be no easy access to an API that can be used by testing frameworks such as JUnit, so the system has to be tested manually by testers inputting test data to the system.

- Systems errors are often subtle and specific to business processes.
 - System testers without detailed knowledge of the end-user processes cannot detect these errors.

Integrated Application Systems

- Integrated application systems are applications that include two or more application system products and/or legacy application systems.

- You may use this approach when there is no single application system that meets all of your needs or when you wish to integrate a new application system with systems that you already use.

Design Choices

- Which individual application systems offer the most appropriate functionality?

  – Typically, there will be several application system products available, which can be combined in different ways.

- How will data be exchanged?

  – Different products normally use unique data structures and formats. You have to write adaptors that convert from one representation to another.

- What features of a product will actually be used?

  – Individual application systems may include more functionality than you need and functionality may be duplicated across different products.

An Integrated Procurement System
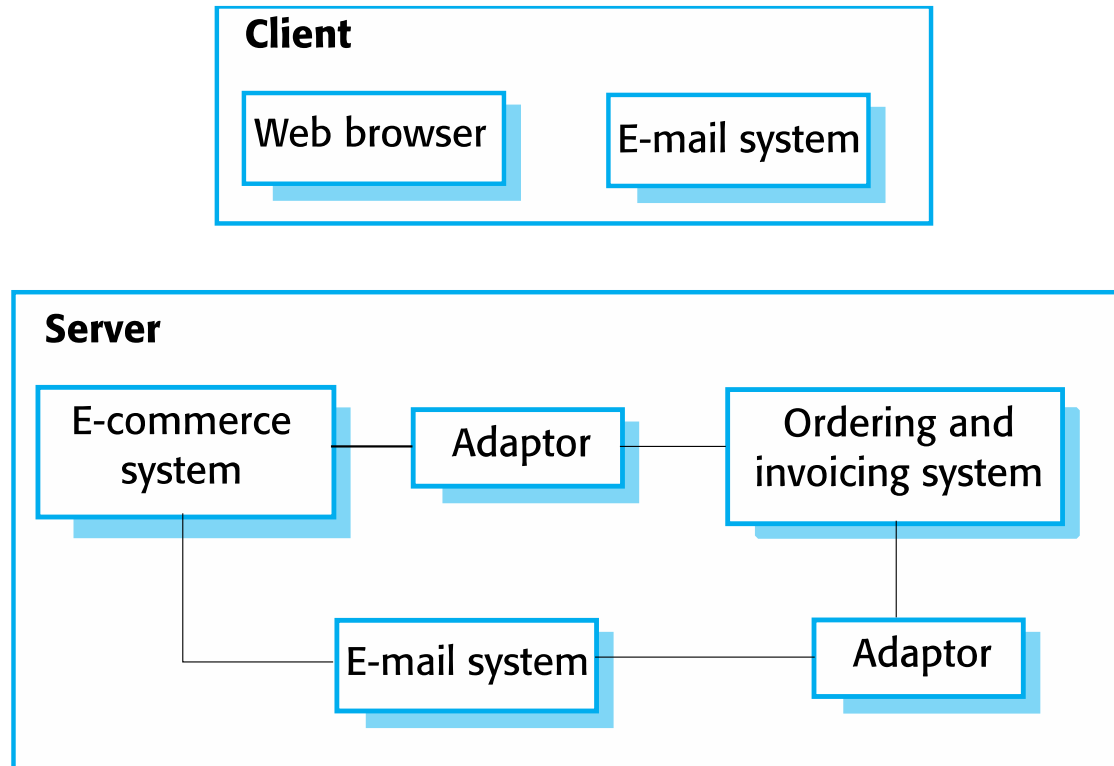

Service-Oriented Interfaces

- Application system integration can be simplified if a service-oriented approach is used.

- A service-oriented approach means allowing access to the application system's functionality through a standard service interface, with a service for each discrete unit of functionality.

- Some applications may offer a service interface but, sometimes, this service interface has to be implemented by the system integrator. You have to program a wrapper that hides the application and provides externally visible services.

Application Wrapping

Service wrapper

Application system

Services

Services
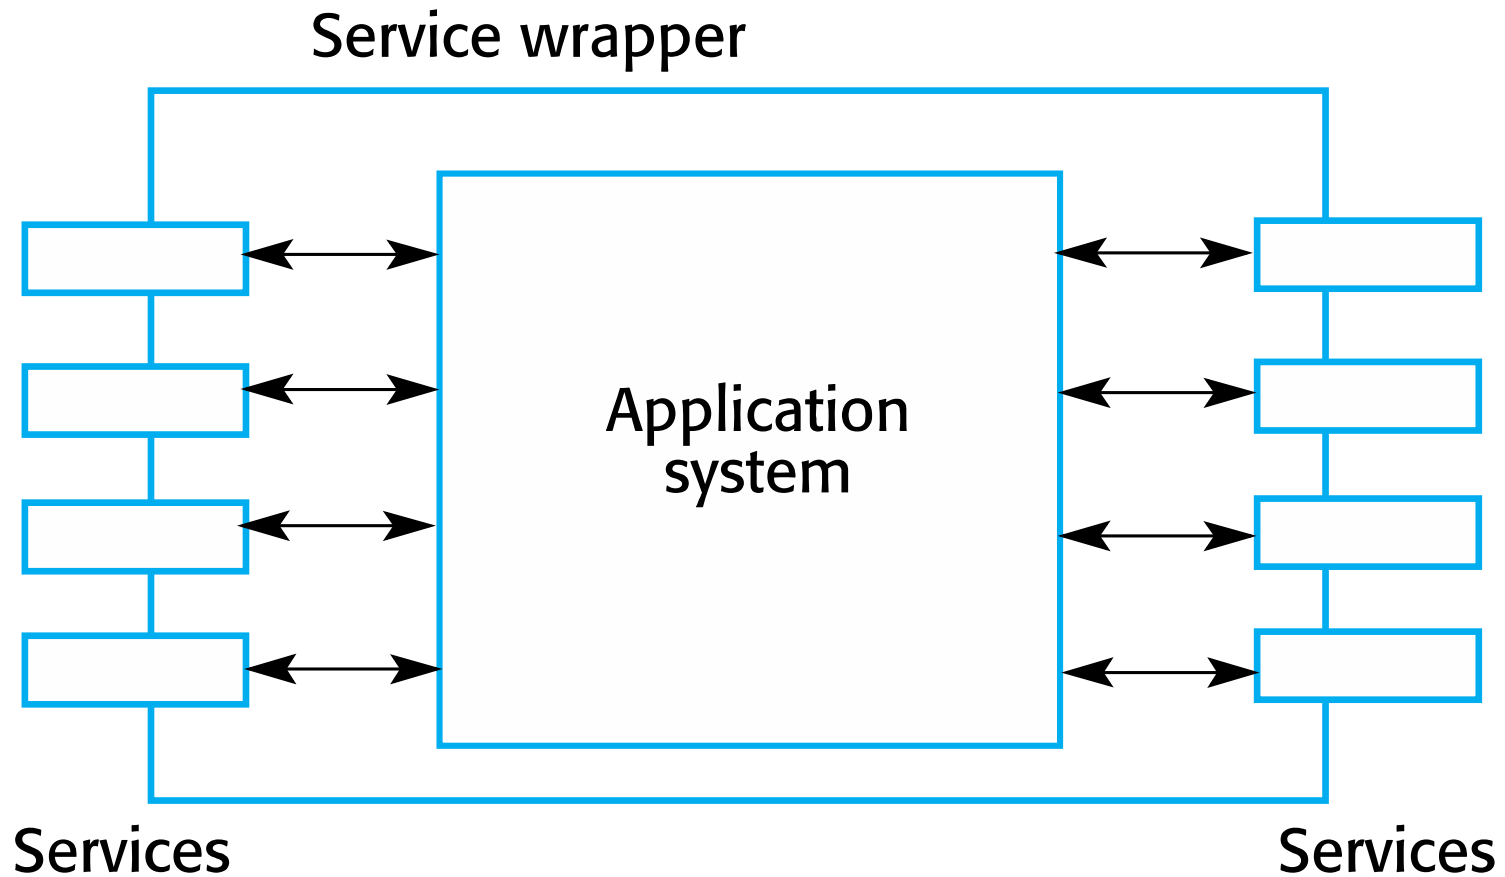

Application System Integration Problems

- Lack of control over functionality and performance
  - Application systems may be less effective than they appear

- Problems with application system inter-operability
  - Different application systems may make different assumptions that means integration is difficult

- No control over system evolution
  - Application system vendors not system users control evolution

- Support from system vendors
  - Application system vendors may not offer support over the lifetime of the product

Key Points (1 of 2)

- There are many different ways to reuse software. These range from the reuse of classes and methods in libraries to the reuse of complete application systems.

- The advantages of software reuse are lower costs, faster software development and lower risks. System dependability is increased. Specialists can be used more effectively by concentrating their expertise on the design of reusable components.

- Application frameworks are collections of concrete and abstract objects that are designed for reuse through specialization and the addition of new objects. They usually incorporate good design practice through design patterns.

Key Points (2 of 2)

- Software product lines are related applications that are developed from one or more base applications. A generic system is adapted and specialized to meet specific requirements for functionality, target platform or operational configuration.

- Application system reuse is concerned with the reuse of large-scale, off-the-shelf systems. These provide a lot of functionality and their reuse can radically reduce costs and development time. Systems may be developed by configuring a single, generic application system or by integrating two or more application systems.

- Potential problems with application system reuse include lack of control over functionality and performance, lack of control over system evolution, the need for support from external vendors and difficulties in ensuring that systems can inter-operate.
